CS 217 – Algorithm Design and Analysis

Shanghai Jiaotong University, Fall 2019

Handed out on Monday, 2019-10-21 First submission and questions due on Monday, 2019-10-28 You will receive feedback from the TA. Final submission due on Monday, 2019-11-04

5 More on Network Flows

Exercise 1. Let G = (V, c) be a flow network. Prove that flow is "transitive" in the following sense: if r, s, t are vertices, and there is an r-s-flow of value k and an s-t-flow of value k, then there is an r-t-flow of value k.

Proof. Denote the original r-s-flow and s-t-flow as f_{rs} and f_{st} respectively, we use them to construct a new r-t-flow f_{rt} , thus prove the transitivity of flow.

Let

$$f_{rt} = V \times V \to \mathbb{R} = \begin{cases} f_{rs}(u, v) & f_{rs}(u, v) \neq 0 \\ f_{st}(u, v) & f_{st}(u, v) \neq 0 \\ 0 & otherwise \end{cases}$$

Here V is the set of all vertices.

We just need to prove f_{rt} is a flow.

• Capacity constraint:

Case1: $f_{rs}(u,v) \neq 0$, then $f_{rt}(u,v) = f_{rs}(u,v) \leq c(u,v)$

Case2: $f_{st}(u, v) \neq 0$, then $f_{rt}(u, v) = f_{st}(u, v) \leq c(u, v)$

Case3: Otherwise, $f_{rt}(u, v) = 0 \le c(u, v)$, since $c(u, v) \ge 0$

• Skew symmetry:

Case1:
$$f_{rs}(u, v) \neq 0$$
, then $f_{rt}(u, v) = f_{rs}(u, v) = -f_{rs}(v, u) = -f_{rt}(v, u)$
Case2: $f_{st}(u, v) \neq 0$, then $f_{rt}(u, v) = f_{st}(u, v) = -f_{st}(v, u) = -f_{rt}(v, u)$
Case3: Otherwise, $f_{rs}(u, v) = 0$, $f_{st}(u, v) = 0 \Rightarrow f_{rt}(u, v) = 0$
 $f_{rs}(v, u) = -f_{rs}(u, v) = 0$, $f_{st}(v, u) = 0 \Rightarrow f_{rt}(v, u) = 0$
 $f_{rt}(u, v) = 0 = -f_{rt}(v, u)$

• Flow conservation: For all $u \in V/\{r, t\}$,

$$\sum_{v \in V} f_{rt}(u, v) = \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) > 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v) + \sum_{v \in V, f_{rs}(u, v) < 0} f_{rt}(u, v)$$

5.1 Vertex Disjoint Paths

Let G be a directed graph. Two paths p_1, p_2 from s to t are called *vertex disjoint* if they don't share any vertices except s and t.

Theorem 2 (Menger's Theorem). Let G be a graph and $s \neq t$ two vertices therein. Let $k \in \mathbb{N}_0$. Then exactly one of the following is true:

- 1. There are k vertex disjoint paths p_1, \ldots, p_k from s to t; that is, no two p_i, p_j share any vertex besides s and t.
- 2. There are vertices $v_1, \ldots, v_k \in V \setminus \{s, t\}$ such that $G \{v_1, \ldots, v_k\}$ contains no s-t-path.

Exercise 3. Prove Menger's Theorem. You have to prove two things: first, not both cases above can occur (this is rather easy); second, one of them must occur (this requires a tool from the lecture).

Proof. First we prove the easy part, these two cases will not occur simultaneously. Prove it by contradiction.

Suppose both cases are true simultaneously, then there are k vertex disjoint paths $p_1, ..., p_k$ from s to t. and there exists $v_1, ..., v_{k-1}$ such that $G - \{v_1, ..., v_{k-1}\}$ contains no s-t-path.

For any $v_1, ..., v_{k-1}$, the can take place in at most k-1 paths in $p_1, ..., p_k$ since $p_1, ..., p_k$ are disjoint vertex paths. Then we know there must be at least one path from $p_1, ..., p_k$ left, which connects s and t, leading to a contradiction.

Next we prove that one of them must occur.

The second case is obvious since we can just remove all vertices except s, t from the V, then obviously there're no s-t-path now.

For the first case, we construct such network-graph. Edges connecting with s,t are assigned with ∞ capacity so that it will not affect the inner flow. All other edges are assigned with capacity 1.

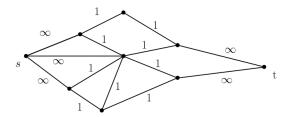

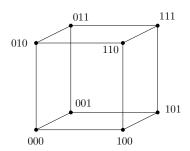

Figure 1: network

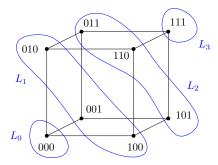

In such a network, the value of a flow is the number of vertex disjoint paths in such a flow. Since the capacity of each edge is 1, we can know for sure that no two s-t-path cross with each other, otherwise there must be a vertex with units bigger than 1. Based on that, we see k, the value of a flow is the number of paths in it. Thus leading to k disjoint paths.

Let $V = \{0,1\}^n$. The *n*-dimensional Hamming cube H_n is the graph (V,E) where $\{u,v\} \in E$ if u,v differ in exactly one coordinate. Define the ith level of H_n as

$$L_i := \{ u \in V \mid ||u||_1 = i \} ,$$

i.e., those vertices u having exactly i coordinates which are 1.

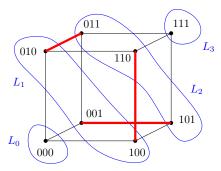

The 3-dimensional Hamming cube and the four sets L_0 , L_1 , L_2 , L_3 .

Exercise 4. [Matchings in H_n] Consider the induced bipartite subgraph $H_n[L_i \cup L_{i+1}]$. This is the graph on vertex set $L_i \cup L_{i+1}$ where two edges are connected by an edge if and only if they are connected in H_n .

Show that for $i \leq n/2$ the graph $H_n[L_i \cup L_{i+1}]$ has a matching of size $|L_i| = \binom{n}{i}$.

A matching of size 3 between L_1 and L_2 .

Proof. Consider $v \in L_i$, we know there are i bits to be 1. Let a_1, a_2, \ldots, a_i be that set of integers or indexes such that $\forall j \leq i, v_{a_j} = 1$. That is, we use the indexes in which v has value 1 to represent the vertex.

Our goal is to construct a mapping $g : \{\mathbb{N} \times ... \times \mathbb{N}\} \to \mathbb{N}$, such that $\{v_1, ..., v_i, g(v)\} = \{\mathbf{v}, g(v)\} \in L_{i+1}$, plus $\forall u \neq v \in L_i$, we have

$${u, g(u)} \neq {v, g(v)}.$$

Let $n = \prod_{i=1}^n p_i^{\alpha_i}$, consider the smallest prime $p \notin \{p_1, \dots, p_n\}$, we construct the mapping g as following:

$$g(u) = (p-1)\left(\sum_{j=1}^{i} u_j\right) \bmod n.$$

We assume u maps to n if g(u) = 0. Now we prove this mapping is valid. Otherwise, there exists u, v they have at least 1 different elements, i.e.

$$|i - |u \cap v| \ge 1$$
.

Plus $\{u, g(u)\} = \{v, g(v)\}$. We must have

$$|u \cap v| = i - 2.$$

Assume $u = \{a_1, \dots, a_{i-1}, g(v)\}, v = \{a_1, \dots a_{i-1}, g(u)\}.$ Hence

$$g(u) = (p-1) \left(\sum_{j=1}^{i-1} a_i + g(v) \right) \mod n$$

$$g(v) = (p-1) \left(\sum_{j=1}^{i-1} a_i + g(u) \right) \mod n.$$

Which leads that

$$p(g(u) - g(v)) = 0 \pmod{n}.$$

Hence

$$u = \{a_1, \dots, a_{i-1}, g(v)\} = \{a_1, \dots, a_{i-1}, g(u)\} = v.$$

It contradicts with the assumption that $u \neq v$, thus the mapping g is a valid one. And $H_n[L_i \cap L_{i+1}]$ has a matching!

Exercise 5. Let H_n be the *n*-dimensional Hamming cube. For i < n/2 consider L_i and L_{n-i} . Note that $|L_i| = \binom{n}{i} = \binom{n}{n-i} = L_{n-i}$, so the L_i and L_{n-i} have the same size. Show that there are $\binom{n}{i}$ paths $p_1, p_2, \ldots, p_{\binom{n}{i}}$ in H_n such that (i) each p_i starts in L_i and ends in L_{n-i} ; (ii) two different paths p_i, p_j do not share any vertices. **Hint 1.** Model this problem as a network flow with vertex capacities. What would the maximum flow be in this network? **Hint 2.** It's not that easy. If you try to work from both sides towards the middle by combining matchings between levels, you will certainly run into problems as how to glue things together in the middle. I have never seen any "meet in the middle" proof that works. **Hint 3.** There is a "direct" proof by induction that does not require anything about network flows.

Proof. It is well known that $\binom{i}{n} \leq \binom{i+1}{n} \leq \ldots \leq \binom{\frac{n}{2}}{n}$. We construct a graph with $s, t, L_i, \ldots, L_{n-i}$. While s connects every vertex in L_i , t connects every vertex in L_{n-i} .

And each edge connects $L_k, L_{k+1}, i \leq k \leq n-i$ has capacity 1. It's clear that the maxflow is less than $|L_i|$.

Plus if maxflow equals $|L_i|$ we are done.

5.2 Matchings and Vertex Covers

The following exercise was on the final exam of CS 499 (mathematical foundations of computer science) in spring 2019.

Exercise 6. Let $\nu(G)$ denote the size of a maximum matching of G. Show that a bipartite graph G has at most $2^{\nu(G)}$ minimum vertex covers.

Proof. Suppose the number of minumum vertex covers of grapg G is m(G). We can easily Now we prove that there could be no more than $2^{\nu(G)}$ minimum

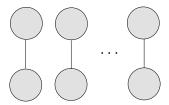

Figure 2: example

vertex cover. Let $G = A \cup B$, since G is a bipartite graph. Assume that the maximum matching is e_1, e_2, \ldots, e_t , in which $t = \nu(G)$. By **Konig's Theorem** we know that the number of vertices in a minimum vertex cover is exactly t.

Plus we can prove that every vertex in K, the vertex cover, is an endpoint of a matched edge. Hence the result is obvious.

Obviously, this is not true for general (non-bipartite) graphs: the triangle K_3 has $\nu(K_3) = 1$ but it has three minimum vertex covers. The five-cycle C_5 has $\nu(C_5) = 2$ but has five minimum vertex covers.

Exercise 7. Is there a function $f: \mathbf{N}_0 \to \mathbf{N}_0$ such that every graph with $\nu(G) = k$ has at most f(k) minimum vertex covers? How small a function f can you obtain?

Proof. Since this is for every graph. First consider K_{2r+1} , we have $\frac{k}{r} K_{2r+1}$. Hence $\nu(G) = \frac{k}{r} \cdot r = k$

$$f(k) > (2r+1)^{\frac{k}{r}}$$
.

For example, if we choose r=1, there are k K_3 , we have $f(k) \geq 3^k$. And let $r \to \infty$ we have

$$f\left(k\right) \ge e^{2k}.$$

Next we prove that the number of minimum vertex cover is at most e^{2k} . Consider \forall minimum vertex cover K. We prove

$$|K| \le e^{2k}.$$

Let $\forall u, v \in K$. If u, v are connected, then at least one of them is on a edge of maximum matching.
